

Customer Support Platform

Frontend Assignment - React and Angular

Business Requirements Document

Document Version	1.0
Delivery Period	4 calendar days
Purpose	Candidate analysis and implementation

1. Business Context

Customers currently report issues through several communication channels and have no single place to follow progress. The support team also lacks one operational view of requests, ownership, urgency, and customer communication.

The company wants two connected experiences using the same business data: a customer portal and a support-team workspace.

2. Business Goals

- Give customers a simple way to submit and follow support requests.
- Help support employees identify requests that require attention.
- Make ownership, urgency, and progress clear.
- Keep customer conversations and internal team notes connected to each request.
- Provide a professional experience across desktop and smaller screens.
- Protect customer information and internal support communication.

3. Customer Experience - React

The React application represents the customer-facing portal.

- A customer can sign in and submit a support request.
- A customer can view only their own requests.
- The customer can understand which requests are active, waiting for them, or completed.
- The customer can open a request, review the conversation, and provide additional information.
- The customer can view the resolution when the issue has been handled.
- The portal should communicate progress in customer-friendly language.

4. Support Experience - Angular

The Angular application represents the operational workspace used by support agents and support managers.

- Support employees can view requests requiring attention.
- They can identify urgent, unassigned, and recently updated requests.
- An agent can take responsibility for an available request.
- An agent can communicate with the customer and add internal team notes.
- An agent can update the request as work progresses and complete it when resolved.
- A support manager can review the full workload and move responsibility between agents when required.

5. Shared Business Process

1. The customer submits a request.
2. The request becomes visible to the support team.
3. A support employee becomes responsible for it.
4. The issue is investigated and additional customer information may be requested.
5. The customer responds through the portal.
6. The support team resolves and completes the request.
7. The request may become active again when further assistance is needed.

6. Business Requirements

- Both applications must operate on the same support-request data.
- Every request should have a unique reference, description, category, urgency, progress, customer, responsible employee when assigned, and activity dates.
- Customer information and requests must be isolated from other customers.

- Internal support notes must never be visible to customers.
- The experience should prevent or handle actions that do not make sense for the current request state.
- The support workspace should allow practical searching, filtering, sorting, and browsing of growing request data.
- Important actions should provide clear confirmation, success, failure, empty, and loading feedback.
- Protected information must remain protected even when a user attempts to access it directly.
- The experience should be responsive, consistent, and suitable for a real business application.

7. Delivery Expectations

Build the customer portal using React and the support workspace using Angular. Both applications should be runnable and demonstrate the shared business workflow. The candidate is responsible for selecting and preparing a suitable shared data source and documenting all required setup.

- Source code for both applications in a Git repository.
- A working shared data source with repeatable setup instructions.
- Clear local run instructions and safe configuration examples.
- Test users or documented user-creation steps.
- A brief record of assumptions, decisions, known limitations, and incomplete items.
- Screenshots or a short recorded demonstration.
- A commit history that reflects the implementation progress.

8. Optional Business Enhancements

These items are optional and should only be considered after the main customer and support workflows are complete.

- Live updates when a request changes.
- Request attachments.
- A manager workload summary.
- Saved filters for support employees.
- Notifications for new replies or responsibility changes.
- Customer feedback after request completion.
- Accessibility improvements beyond the basic experience.
- A deployed demonstration environment.
